Abstract

We study the neutron electric dipole moment (EDM) in a five dimensional $SU(3)$ gauge-Higgs unification compactified on $M^4 \times S^1/Z_2$ space-time including a massive fermion. We point out that to realize the CP violation is a non-trivial task in the gauge-Higgs unification scenario and argue how the CP symmetry is broken spontaneously by the VEV of the Higgs, the extra space component of the gauge field. We emphasize the importance of the interplay between the VEV of the Higgs and the Z_2 -odd bulk mass term to get physically the CP violation. We then calculate the one-loop contributions to the neutron EDM as the typical example of the CP violating observable and find that the EDM appears already at the one-loop level, without invoking to the three generation scheme. We then derive a lower bound for the compactification scale, which is around 2.6 TeV, by comparing the contribution due to the nonzero Kaluza-Klein modes with the experimental data.

1 Introduction

Gauge-Higgs unification scenario proposed long time ago [1, 2, 3, 4] has attracted recent revived interest as one of the attractive scenarios solving the hierarchy problem without invoking supersymmetry. In this scenario, Higgs doublet in the Standard Model (SM) is identified with the extra spatial components of the higher dimensional gauge fields. Remarkable feature is that the quantum correction to Higgs mass is finite and insensitive to the cutoff scale of the theory, in spite of the fact that higher dimensional gauge theories are generally non-renormalizable. The reason is simply that the Higgs mass-squared term as a local operator is forbidden by the higher dimensional gauge invariance. The radiatively induced finite Higgs mass should be understood as to be described by the Wilson line phase, that is a non-local operator and free from UV-divergence. This fact has opened up a new avenue to the solution of the hierarchy problem [5]. Since then, much attention has been paid to the gauge-Higgs unification and many interesting works have been done from various points of view [6]-[29].

The finiteness of Higgs mass has been studied and verified in various models and types of compactification at one-loop level [30]-[33]¹ and even at two loop level [35]. It is natural to ask whether any other finite calculable physical observables exist in the gauge-Higgs unification. In a paper by the present authors [36], we have found a striking fact: we have shown that the anomalous magnetic moment of fermion in the $(D + 1)$ dimensional QED gauge-Higgs unification model compactified on S^1 becomes finite for an arbitrary space-time dimension. The reason is easily understood relying on an operator analysis. In four dimensional space-time, a dimension six gauge invariant local operator describes the anomalous magnetic moment:

$$i\bar{\psi}_L\sigma^{\mu\nu}\psi_RF_{\mu\nu}\langle H\rangle. \quad (1.1)$$

However, when included into the scheme of gauge-Higgs unification, the Higgs doublet should be replaced by an extra space component of the higher dimensional gauge field A_y . Then, to preserve the gauge symmetry, A_y should be further replaced by gauge covariant derivative D_y , and the relevant gauge invariant operator becomes

$$i\bar{\Psi}\Gamma^{MN}D_L\Gamma^L\Psi F_{MN} \quad (1.2)$$

where L, M and N denote $(D + 1)$ dimensional Lorentz indices. The key observation of our argument is that the operator (1.2), when D_L is replaced by $\langle D_L \rangle$ with the gauge field A_L replaced by its VEV, vanishes because of the on-shell condition $i\langle D_L \rangle\Gamma^L\Psi = 0$. As the local operator is forbidden, the anomalous magnetic moment is expected to be free from the UV-divergence. We confirmed the finiteness of the magnetic moment by an explicit diagrammatical calculations [36]. This is a remarkable specific prediction of the gauge-Higgs unification to be contrasted with the case of Randall-Sundrum model [37] or the universal extra dimension scenario [38], in which the magnetic moment of fermion diverges in the models with more than five space-time dimensions.

¹For the case of gravity-gauge-Higgs unification, see [34]

Although this result was quite impressive, the above model is too simple to be realistic. In particular, the famous result by Schwinger in ordinary QED could not be reproduced as the contribution of zero-modes in the simplified model. Thus, in our following paper [39], we have clarified the issue on cancellation mechanism of ultraviolet (UV) divergences in a realistic gauge-Higgs unification model. What we adopted was $(D + 1)$ dimensional $SU(3)$ gauge-Higgs unification model compactified on an orbifold S^1/Z_2 with a massive bulk fermion in a fundamental representation, whose gauge group is large enough to incorporate that of the Standard Model. The orbifolding is indispensable to obtain chiral theory and to reduce the gauge symmetry to that of the Standard Model. In order to obtain a realistic Yukawa coupling we introduced a bulk mass parameter of fermion, which should have odd Z_2 parity in order to preserve the Z_2 symmetry. The bulk mass causes localization of fermions with different chiralities at different fixed points of the orbifold. Hence the overlap integral of their mode functions yields an exponentially suppressed Yukawa coupling. In this way, we can freely obtain the light fermion masses, which are otherwise of $\mathcal{O}(M_W)$ in the gauge-Higgs unification scenario, by tuning the bulk mass parameters. We thus have succeeded in recovering the Schwinger's result, still keeping the nice feature of the scenario, i.e. the anomalous moment was shown to be finite even in 6 dimensional space-time, where other higher dimensional theories such as universal extra dimension scenario give divergent results. In the most recent paper [40], we also have performed numerical calculations to obtain the contribution of non-zero KK modes to the muon anomalous magnetic moment and have derived a useful constraint on the compactification scale by comparing the result with the experimental data.

In this paper, we focus on the CP violation in the gauge-Higgs unification scenario. As the concrete example of the physical observable due to the CP violation we discuss the neutron electric dipole moment (EDM) whose computation has some similarity to that of the anomalous magnetic moment of fermions. We will work in the same model as in the previous paper [40], i.e. the 5 dimensional $SU(3)$ gauge-Higgs unification model compactified on an orbifold S^1/Z_2 with a massive bulk fermion in a fundamental representation.

Let us note that how to break CP symmetry is a non-trivial question in the gauge-Higgs unification scenario, since the Higgs field is nothing but a gauge field to start with and its Yukawa coupling is originally gauge coupling, which is real. As far as the theory itself has CP symmetry, the possible way to break CP is due to the compactification which does not respect the symmetry as in the case of Calabi-Yau manifold with non-trivial complex structure [41] or by the VEV of some field which has odd CP eigenvalue [42]. Both mechanisms may be understood as (a sort of) spontaneous CP violation, since the theory itself preserves the CP symmetry and the way of the compactification is responsible for the determination of the vacuum state. (In fact, the effect of compactification is accompanied by the compactification scale $1/R$, which has a mass dimension and the corresponding CP violation is “soft”.)

In the present model the compactification itself is too simple to break CP, since the orbifold is trivially invariant under a discrete transformation $y \rightarrow -y$ (y : extra space coordinate). Thus the possible unique source to break the CP symmetry is expected to be the VEV of the Higgs field, which

is the zero-mode of A_y , the extra space component of the gauge field.

To see whether this is really the case or not, we argue how the space-time coordinates and each field behave under the P and CP transformations. First, let us note that the EDM is P- and CP-odd observable, and therefore both of P and CP have to be broken to get a non-vanishing EDM. The P and CP transformations in higher dimensional theories need some care. Though we can easily find P and C transformations in higher dimensional sense, they may not reduce to ordinary 4-dimensional P or C transformations when dimensional reduction is performed [41]. In the 5 dimensional space-time, however, the spinor is a 4-component one just as in the 4-dimensional theory and P and C transformations may be defined in the ordinary ways.

First the parity transformation is defined for fermions as

$$P : \Psi \rightarrow \gamma^0 \Psi, \quad (1.3)$$

where Ψ denotes the $SU(3)$ triplet fermion. To be precise, the extra-space coordinate y turns out to be enforced to change its sign for the kinetic term to be invariant under (1.3) and at the first glance it does not seem to correspond to the ordinary 4-dimensional P transformation. However, at least the zero-mode fields corresponding to the ordinary particles in the Standard Model are even functions of y and the change of the sign is irrelevant for the low-energy effective theory. Let us note that in our model the P symmetry is broken anyway by the orbifolding, no matter A_y develops its VEV or not, since the orbifolding is aimed to realize a chiral theory. This may also be known by realizing that the orbifold condition for the fermion

$$\Psi(-y) = P\gamma^5\Psi(y) \quad (P = \text{diag}(+, +, -)) \quad (1.4)$$

is inconsistent with the parity transformation (1.3), since γ^0 does not commute with γ^5 .

Next, combining with the C transformation, $C : \Psi \rightarrow i\gamma^2\Psi^*$, we can derive the CP transformation:

$$CP : \Psi(x^\mu, y) \rightarrow i\gamma^0\gamma^2\Psi(x_\mu, y)^*, \quad (1.5)$$

This time, the transformation is consistent with the condition (1.4), since $\gamma^0\gamma^2$ commutes with γ^5 . Hence, CP is not violated by the orbifolding. The corresponding transformation properties of the space-time coordinates and the gauge field are fixed so that $\bar{\Psi}i\Gamma^M(\partial_M - igA_M)\Psi$ ($\Gamma^M = (\gamma^\mu, i\gamma^5)$, $A_M = (A_\mu, A_y)$ ($\mu = 0 - 3$)) is invariant under (1.5). Namely,

$$CP : x^\mu \rightarrow x_\mu, y \rightarrow y, A_\mu(x^\mu, y) \rightarrow -A^\mu(x_\mu, y)^t, A_y(x^\mu, y) \rightarrow -A_y(x_\mu, y)^t. \quad (1.6)$$

The Z_2 -odd bulk mass term in the lagrangian $-M\epsilon(y)\bar{\Psi}\Psi$ ($\epsilon(y)$: sign function of y) is also invariant under such defined CP transformation, as y remains untouched and $\epsilon(y)$ does not change its sign. Let us note that if the fermions are expanded in terms of the ortho-normal set of plane waves as $\Psi(x^\mu, y) = \sum_n e^{i\frac{n}{R}y}\Psi^{(n)}(x^\mu)$ with R being the radius of the circle (though real mass eigenstates have different mode functions in the presence of the bulk mass M), the CP transformation necessitates the exchange of the KK modes, $n \leftrightarrow -n$, in addition to the 4-dimensional CP transformation for $\Psi^{(n)}(x^\mu)$. Fortunately, this exchange of the KK modes is irrelevant for the zero-mode fermions.

Thus the transformation given in (1.5) and (1.6) just reduce to the ordinary 4-dimensional CP transformation for zero-mode fields.

We thus realize that A_y has CP eigenvalue -1 . Hence, the VEV of A_y is the unique source of the CP violation. As the matter of fact, however, in the case that the Z_2 -odd bulk mass term vanishes, the CP violation is known to disappear even for the non-vanishing VEV of A_y . In fact, in this case, we can perform a chiral transformation, $\Psi \rightarrow e^{i\frac{\pi}{4}\gamma^5}\Psi$ such that $i\gamma^5$ disappears from the covariant derivative term $i\bar{\Psi}\Gamma^5 D_5\Psi$, keeping the other parts of the lagrangian invariant. Now, A_y has a scalar type coupling with fermions and therefore is now even under the CP transformation:

$$\begin{aligned} CP : \quad x^\mu &\rightarrow x_\mu, \ y \rightarrow y, \ \Psi(x^\mu, y) \rightarrow i\gamma^0\gamma^2\Psi(x_\mu, -y)^*, \\ A_\mu(x^\mu, y) &\rightarrow -A^\mu(x_\mu, -y)^t, \ A_y(x^\mu, y) \rightarrow A_y(x_\mu, -y)^t. \end{aligned} \quad (1.7)$$

The invariance of the action under the CP transformation is easily checked by use of the change of the integration variable $y \rightarrow -y$. Thus the VEV of A_y no longer violates CP. Let us note that in this case the exchange of the KK modes is not needed for fermions.

We thus find that to break CP physically and to get a non-vanishing EDM, the interplay between the VEV of A_y and the bulk mass M is crucial, and from such a point of view both of the VEV and the bulk mass are the cause of the CP violation on an equal footing. The necessity of the interplay will be shown by an explicit calculation of Feynman diagrams later in this paper.

Let us note that the VEV of A_y is needed anyway to get the EDM, since the gauge invariant operator to describe the EDM in the standard model is

$$-\frac{i}{2}\bar{\psi}\sigma^{\mu\nu}\gamma^5 F_{\mu\nu}\langle H\rangle\psi, \quad (1.8)$$

which vanishes when $\langle H\rangle$ and therefore the VEV of A_y vanishes. From the same reasoning to conclude that the anomalous magnetic moment is finite even for 6-dimensional space-time, we expect relying on a similar operator analysis that the EDM is also finite even for 6D theory, though in this paper we work in the 5D space-time.

The purposes of this paper are two-folds. One is to confirm that the EDM really appears as a finite calculable observable already at the one-loop level, though the EDM has been shown to appear only at the three loop level in the Standard Model [43]. In addition, in our model we introduce only the first generation and to get the EDM we do not need 3 generation scheme, in clear contrast to the case of the Standard Model. The other one is to obtain the lower bound on the compactification scale, i.e. the upper bound on the size of the extra space, by comparing the prediction of our model with the experimental data.

In ref.[42], CP violation in the gauge-Higgs unification scenario has also been discussed. The gauge group they adopt is a $U(1)$ and the extra space is a circle. In our case, the gauge group is an $SU(3)$ and the extra space is orbifold so that the model can incorporate the chiral theory of the Standard Model. The chiral theory clearly violates the P symmetry, in contrast to the case of $U(1)$ gauge theory discussed in [42]. The introduction of the Z_2 -odd bulk mass term is also a new feature of our model. By adopting such realistic model, we hope that we can derive a realistic prediction for

the neutron EDM to be compared with the data, which is expected to have various new ingredients not seen in the prediction in [42], due to the complexity of our model. Notice that the possibility of the recovery of CP symmetry due to the Wilson line phase π at the minimum of the effective potential for A_y pointed out in [42] has no relevance in our model, as we assume the realistic situation where the weak scale, i.e. the VEV of A_y times gauge coupling is much smaller than the compactification scale $1/R$.

This paper is organized as follows. In the next section, we briefly summarize our model and discuss the mass eigenvalues and corresponding mode functions of fermions and gauge bosons. In section 3, we derive general formulae relevant for EDM concerning a few types of Feynman diagrams where 4D gauge boson A_μ or 4D scalar A_y are exchanged or self-interaction of the 4D gauge and scalar fields is contributing. The coupling constants in the interaction vertices are left arbitrary there. Then combining with the interaction vertices derived in ref. [40] we obtain the contribution of each type of Feynman diagram to EDM. In section 4, we numerically estimate the contribution of nonzero KK modes to the EDM as the function of the compactification scale $1/R$. Comparing with the experimental data we finally obtain a rather stringent lower bound for the compactification scale. Section 5 is devoted to the summary discussion.

2 The Model

Since we employ the same model as that discussed in [39] to calculate EDM, we briefly summarize it in this paper. We consider a five dimensional $SU(3)$ gauge-Higgs unification model compactified on an orbifold S^1/Z_2 with a radius R of S^1 . As a matter field, a massive bulk fermion in the fundamental representation of $SU(3)$ gauge group is introduced. The Lagrangian is given by

$$\mathcal{L} = -\frac{1}{2}\text{Tr}(F_{MN}F^{MN}) + \bar{\Psi}(i\not{D} - M\epsilon(y))\Psi \quad (2.1)$$

where the indices $M, N = 0, 1, 2, 3, 5$, the five dimensional gamma matrices are $\Gamma^M = (\gamma^\mu, i\gamma^5)$ ($\mu = 0, 1, 2, 3$),

$$F_{MN} = \partial_M A_N - \partial_N A_M - ig[A_M, A_N], \quad (2.2)$$

$$\not{D} = \Gamma^M(\partial_M - igA_M), \quad (2.3)$$

$$\Psi = (\Psi_1, \Psi_2, \Psi_3)^T \quad (2.4)$$

g denotes a gauge coupling constant in five dimensional gauge theory. M is a bulk mass of the fermion. $\epsilon(y)$ is a sign function of an extra coordinate y which is necessary to introduce a Z_2 odd bulk mass term.

The periodic boundary condition is imposed along S^1 and Z_2 parity assignments are taken as

$$A_\mu(y_i - y) = PA_\mu(y_i + y)P^\dagger, \quad A_y(y_i - y) = -PA_y(y_i + y)P^\dagger, \quad \Psi(y_i - y) = P\gamma^5\Psi(y_i + y) \quad (2.5)$$

where $P = \text{diag}(+, +, -)$ at fixed points $y_i = 0, \pi R$. By this Z_2 parity assignment, $SU(3)$ is explicitly broken to $SU(2) \times U(1)$. Higgs scalar field is identified with the off-diagonal block of zero mode $A_y^{(0)}$.

The 4-dimensional gauge bosons A_μ and their scalar partners A_y can be expanded in KK modes such that the boundary conditions (2.5) are satisfied,

$$A_{\mu,y}(x, y) = \frac{1}{\sqrt{2\pi R}} A_\mu^{(0)}(x) + \frac{1}{\sqrt{\pi R}} \sum_{n=1}^{\infty} A_{\mu,y}^{(n)}(x) \cos\left(\frac{n}{R}y\right) \quad (\text{even}), \quad (2.6)$$

$$A_{\mu,y}(x, y) = \frac{1}{\sqrt{\pi R}} \sum_{n=1}^{\infty} A_{\mu,y}^{(n)}(x) \sin\left(\frac{n}{R}y\right) \quad (\text{odd}). \quad (2.7)$$

After electroweak symmetry breaking, quadratic terms relevant to the gauge boson mass are diagonalized as

$$\begin{aligned} \mathcal{L}_{\text{mass}} &= \frac{1}{2} \int_{-\pi R}^{\pi R} dy [\partial^\mu A_\mu^a - (\partial_y A_y^a - 2m_W f^{6ab} A_{by})]^2 \\ &= \sum_{n=1}^{\infty} \left[\frac{1}{2} M_n^2 (\gamma_\mu^{(n)} \gamma^{\mu(n)} + h_\mu^{(n)} h^{\mu(n)}) + \frac{1}{2} (M_n - 2m_W)^2 \phi_\mu^{(n)} \phi^{\mu(n)} + \frac{1}{2} (M_n + 2m_W)^2 Z_\mu^{(n)} Z^{\mu(n)} \right. \\ &\quad \left. + (M_n + m_W)^2 W_\mu^{+(n)} W^{-\mu(n)} + (M_n - m_W)^2 X_\mu^{+(n)} X^{-\mu(n)} \right] + \frac{1}{2} (2m_W)^2 Z_\mu Z^\mu + m_W^2 W_\mu^+ W^{-\mu} \\ &\quad - \sum_{n=1}^{\infty} \left[\frac{1}{2} M_n^2 (\gamma_y^{(n)} \gamma_y^{(n)} + h_y^{(n)} h_y^{(n)}) + \frac{1}{2} (M_n + 2m_W)^2 \phi_y^{(n)} \phi_y^{(n)} + \frac{1}{2} (M_n - 2m_W)^2 Z_y^{(n)} Z_y^{(n)} \right. \\ &\quad \left. + (M_n - m_W)^2 W_y^{+(n)} W_y^{-\mu(n)} + (M_n + m_W)^2 X_y^{+(n)} X_y^{-(n)} \right] + \frac{1}{2} (2m_W)^2 Z_y Z_y + m_W^2 W_y^+ W_y^- \end{aligned} \quad (2.8)$$

where the gauge-fixing term in 't Hooft-Feynman gauge is introduced to eliminate the mixing terms between the gauge bosons and the gauge scalar bosons. $M_n = \frac{n}{R}$, $m_W = 2g\langle A_y^6 \rangle = \frac{g}{\sqrt{2\pi R}} v = g_4 v$. g_4 is a four dimensional gauge coupling. The KK mass eigenstates and zero mode mass eigenstates are given by

$$\begin{aligned} \gamma^{(n)} &= \frac{1}{2} (\sqrt{3} A^{3(n)} + A^{8(n)}), & h^{(n)} &= A^{6(n)}, \\ Z^{(n)} &= \frac{1}{\sqrt{2}} \left[\frac{A^{3(n)} - \sqrt{3} A^{8(n)}}{2} - A^{7(n)} \right], & \phi^{(n)} &= \frac{1}{\sqrt{2}} \left[\frac{A^{3(n)} - \sqrt{3} A^{8(n)}}{2} + A^{7(n)} \right], \\ W^{\pm(n)} &= \frac{1}{2} [A^{1(n)} + A^{5(n)} \mp i(A^{2(n)} - A^{4(n)})], & X^{\pm(n)} &= \frac{1}{2} [A^{2(n)} + A^{4(n)} \mp i(-A^{1(n)} + A^{5(n)})], \\ \gamma_\mu &= \frac{1}{2} [\sqrt{3} A_\mu^3 + A_\mu^8], & h &= A_y^{6(0)}, \\ W_\mu^\pm &= \frac{1}{\sqrt{2}} (A_\mu^1 \mp i A_\mu^2), & X^\pm &= \frac{1}{\sqrt{2}} [A_y^4 \mp i A_y^5], \\ Z_\mu &= \frac{1}{2} (A_\mu^3 - \sqrt{3} A_\mu^8), & \phi &= A_y^7. \end{aligned} \quad (2.9)$$

The zero mode gauge bosons $W_\mu^\pm, Z_\mu, \gamma_\mu$ correspond to W boson, Z boson and photon and zero mode scalar fields $X^\pm, \phi, h$ correspond to charged NG boson, neutral NG boson, Higgs field in the Standard Model, respectively.

Some comments on this model are in order. First, the predicted Weinberg angle of this model is not realistic, $\sin^2 \theta_W = 3/4$ [45]. Possible way to cure the problem is to introduce an extra $U(1)$ or the brane localized gauge kinetic term [10]. Second, the up quark remains massless and we have no up-type Yukawa coupling. A possible way out of this situation is to introduce second-rank symmetric tensors of $SU(3)$ (6 dimensional representation) [16].

On the other hand, we have obtained a quadratic part of 4D effective Lagrangian of fermion

$$\mathcal{L} = \sum_{n=1}^{\infty} \left[\bar{\psi}_1^{(n)} (i\partial - m_n) \psi_1^{(n)} + \bar{\psi}_2^{(n)} (i\partial - m_n^-) \psi_2^{(n)} + \bar{\psi}_3^{(n)} (i\partial - m_n^+) \psi_3^{(n)} \right] + \bar{d} (i\partial - m) d + \bar{u}_L i\partial u_L. \quad (2.10)$$

where the mass eigenstates of fermion were obtained as:

$$d_L = \Psi_{2L}^{(0)} + \sum_{n=1}^{\infty} \frac{\hat{m}_n}{m_n} \Psi_{3L}^{(n)}, \quad d_R = \Psi_{3R}^{(0)} + \sum_{n=1}^{\infty} (-1)^n \frac{\hat{m}_n}{m_n} \Psi_{3R}^{(n)}, \quad (2.11)$$

$$\psi_{3L}^{(n)} = \frac{1}{\sqrt{2}} \left[\Psi_{2L}^{(n)} + \Psi_{3L}^{(n)} + \frac{M^2}{2m_n^3} m_W (\Psi_{2L}^{(n)} - \Psi_{3L}^{(n)}) - \frac{\hat{m}_n}{m_n} \Psi_{2L}^{(0)} + \sum_{l \neq n}^{\infty} \frac{\tilde{m}_{nl}}{m_n^2 - m_l^2} (m_l \Psi_{3L}^{(l)} - m_n \Psi_{2L}^{(l)}) \right], \quad (2.12)$$

$$\psi_{2L}^{(n)} = \frac{1}{\sqrt{2}} \left[\Psi_{2L}^{(n)} - \Psi_{3L}^{(n)} - \frac{M^2}{2m_n^3} m_W (\Psi_{2L}^{(n)} - \Psi_{3L}^{(n)}) + \frac{\hat{m}_n}{m_n} \Psi_{2L}^{(0)} + \sum_{l \neq n}^{\infty} \frac{\tilde{m}_{nl}}{m_n^2 - m_l^2} (m_l \Psi_{3L}^{(l)} + m_n \Psi_{2L}^{(l)}) \right], \quad (2.13)$$

$$\psi_{3R}^{(n)} = \frac{1}{\sqrt{2}} \left[\Psi_{2R}^{(n)} + \Psi_{3R}^{(n)} - \frac{M^2}{2m_n^3} m_W (\Psi_{2L}^{(n)} - \Psi_{3L}^{(n)}) - (-1)^n \frac{\hat{m}_n}{m_n} \Psi_{2L}^{(0)} + \sum_{l \neq n}^{\infty} \frac{\tilde{m}_{nl}}{m_n^2 - m_l^2} (m_n \Psi_{3R}^{(l)} - m_l \Psi_{2R}^{(l)}) \right], \quad (2.14)$$

$$\psi_{2R}^{(n)} = \frac{1}{\sqrt{2}} \left[\Psi_{2R}^{(n)} - \Psi_{3R}^{(n)} - \frac{M^2}{2m_n^3} m_W (\Psi_{2L}^{(n)} - \Psi_{3L}^{(n)}) + \frac{\hat{m}_n}{m_n} \Psi_{2R}^{(0)} + \sum_{l \neq n}^{\infty} \frac{\tilde{m}_{nl}}{m_n^2 - m_l^2} (m_l \Psi_{3R}^{(l)} + m_n \Psi_{2R}^{(l)}) \right], \quad (2.15)$$

$$u_L = \Psi_{1L}^{(0)}, \quad \psi_1^{(n)} = \Psi_1^{(n)}. \quad (2.16)$$

where

$$\begin{aligned} m &= \frac{2\pi RM}{\sqrt{(1-e^{-2\pi RM})(e^{2\pi RM}-1)}} m_W, & \tilde{m}_{Wn} &= \left(1 - \frac{2M^2}{m_n^2}\right) m_W, \\ \hat{m}_n &= 4\sqrt{\frac{\pi RM}{1-e^{-2\pi RM}}} \frac{1-(-1)^n e^{-\pi RM}}{\pi R m_n^3} M_n M m_W, & \tilde{m}_n &= (-1)^n \hat{m}_n, \\ \tilde{m}_{nl} &= \frac{4nl(1-(-1)^{n+l})}{\pi R m_n m_l (n^2-l^2)} (1 - \delta_{nl}) m_W M, & (m_n^{\pm})^2 &= m_n^2 \pm 2m_W \frac{M_n^2}{m_n}. \end{aligned} \quad (2.17)$$

In deriving the above 4D effective Lagrangian of fermion, the following mode expansions are substituted and integrated out over the fifth coordinate.

$$\Psi(x, y) = \sum_{n=1}^{\infty} \begin{pmatrix} \Psi_{1L}^{(n)}(x) f_L^{(n)}(y) + \Psi_{1R}^{(n)}(x) g^{(n)}(y) \\ \Psi_{2L}^{(n)}(x) f_L^{(n)}(y) + \Psi_{2R}^{(n)}(x) g^{(n)}(y) \\ \Psi_{3L}^{(n)}(x) g^{(n)}(y) + \Psi_{3R}^{(n)}(x) f_R^{(n)}(y) \end{pmatrix} + \begin{pmatrix} \Psi_{1L}^{(0)}(x) f_L^{(0)}(y) \\ \Psi_{2L}^{(0)}(x) f_L^{(0)}(y) \\ \Psi_{3R}^{(0)}(x) f_R^{(0)}(y) \end{pmatrix} \quad (2.18)$$

with the zero mode wave functions

$$f_L^{(0)} = \sqrt{\frac{M}{1-e^{-2\pi RM}}} e^{-M|y|}, \quad f_R^{(0)} = \sqrt{\frac{M}{e^{2\pi RM}-1}} e^{M|y|}. \quad (2.19)$$

and the nonzero KK mode functions

$$f_L^{(n)} = \frac{M_n}{\sqrt{\pi R m_n}} \left[\cos\left(\frac{n}{R}y\right) - \frac{MR}{n} \epsilon(y) \sin\left(\frac{n}{R}y\right) \right], \quad (2.20)$$

$$f_R^{(n)} = \frac{M_n}{\sqrt{\pi R m_n}} \left[\cos\left(\frac{n}{R}y\right) + \frac{MR}{n} \epsilon(y) \sin\left(\frac{n}{R}y\right) \right], \quad (2.21)$$

$$g^{(n)} = \frac{1}{\sqrt{\pi R}} \sin\left(\frac{n}{R}y\right). \quad (2.22)$$

Deriving the vertex functions necessary for calculating the neutron EDM by using the above mass eigenfunctions is straightforward, but complicated. We do not repeat here their derivation since the necessary vertex functions are the exactly same ones as summarized in Appendix A of our previous paper [40], except that the muon μ should be replaced by the down quark d .

3 Calculation of the electric dipole moment

In this section, we provide general formulae to calculate fermion EDM. Various types of diagrams contributing to the EDM are written down below. Fermion electric dipole moment is described by dimension 6 operator $-\frac{i}{2}\bar{\psi}_L(p')\sigma^{\nu\rho}\gamma^5 F_{\nu\rho}\langle H\rangle\psi_R(p)$. In general, quantum corrections to the photon vertex $-\frac{e}{3}\gamma_\rho\bar{\psi}(p')\gamma^\rho\psi(p)$ can be written as

$$-i\frac{e}{3}\gamma_\mu\bar{\psi}(p')[\gamma^\mu + \Gamma^\mu]\psi(p) \quad (3.1)$$

where

$$\Gamma^\mu = a_\psi \frac{p^\mu + p'^\mu}{2m_\psi} + \frac{d_\psi}{e/3}(p^\mu + p'^\mu)\gamma_5.$$

a_ψ and d_ψ stand for the anomalous magnetic moment and the electric dipole moment of ψ , respectively. Since our interest in this paper is in the electric dipole moment, the terms proportional to $\gamma_5(p_\mu + p'_\mu)$ must be extracted.

We now derive general formulae for each type of Feynman diagram, leaving the couplings in the interaction vertices arbitrary. First, the gauge boson exchange diagram is given by (a, b, c, d are generic coupling constants)

$$\begin{aligned} \text{Diagram} &= \int \frac{d^4 k}{(2\pi)^4 i} (aL + bR) \gamma^\nu \frac{-1}{\not{k} + \not{p}' - m_n} (Q_\psi \gamma_\mu) \frac{-1}{\not{k} + \not{p} - m_n} \gamma_\nu (cL + dR) \frac{1}{k^2 - M_G^2} \\ &\supset -Q_\psi \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{4(ac - bd)(1 - X)m_n}{[k^2 + X(1 - X)m^2 - Xm_n^2 - (1 - X)M_G^2]^3} \gamma_5 P_\mu. \end{aligned} \quad (3.2)$$

In the second line only the part relevant for the EDM has been extracted. Similarly the diagram due

to the exchange of the scalar partner of gauge boson given by

$$\begin{aligned}
&= \int \frac{d^4 k}{(2\pi)^4 i} (aL + bR) \frac{-1}{\not{k} + \not{p}' - m_n} (Q_\psi \gamma_\mu) \frac{-1}{\not{k} + \not{p} - m_n} (cL + dR) \frac{-1}{k^2 - m_G^2} \\
&\supset -Q_\psi \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{-(ac - bd) X m_n}{[k^2 - X^2 m^2 + X m^2 - X m_n^2 - (1 - X) M_G^2]^3} \gamma_5 P^\mu. \quad (3.3)
\end{aligned}$$

For the diagrams due to the gauge boson self-energy, there are following three types of diagrams.

$$\begin{aligned}
&= \int \frac{d^4 k}{(2\pi)^4 i} (aL + bR) \gamma_\rho \frac{-1}{\not{k} - m_n} \gamma_\nu (cL + dR) \frac{1}{(k - p')^2 - M_G^2} \frac{1}{(k - p)^2 - M_G^2} \\
&\quad \times (-e)[(2p' - p - k)_\rho \eta_{\mu\nu} + (2k - p' - p)_\mu \eta_{\nu\rho} + (2p - p' - k)_\nu \eta_{\mu\rho}] \\
&\supset e \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{-(ac - bd)[X + 2 + 4(1 - X)] m_n}{[k^2 + X(1 - X)m^2 - X M_G^2 - (1 - X)m_n^2]^3} \gamma_5 P^\mu, \quad (3.4)
\end{aligned}$$

$$\begin{aligned}
&= \int \frac{d^4 k}{(2\pi)^4 i} (aL + bR) \frac{-1}{\not{k} - m_n} (cL + dR) \frac{-1}{(k - p')^2 - M_G^2} \frac{-1}{(k - p)^2 - M_G^2} e(2k - p' - p)_\mu \\
&\supset -e \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{-(ac - bd)(1 - X)m_n}{[k^2 + X(1 - X)m^2 - X M_G^2 - (1 - X)m_n^2]^3} \gamma_5 P_\mu, \quad (3.5)
\end{aligned}$$

$$\begin{aligned}
&+ (\text{h.c.}) = \int \frac{d^4 k}{(2\pi)^4 i} (aL + bR) \gamma^\mu \frac{-1}{\not{k} - m_n} (cL + dR) \frac{1}{(k - p')^2 - M_G^2} \frac{-1}{(p - k)^2 - M_G^2} \\
&\quad \times (\pm e) M_G + (\text{h.c.}) \\
&= \pm e \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{(ac - bd)(x - y) M_G}{[k^2 + X(1 - X)m^2 - X M_G^2 - (1 - X)m_n^2]^3} \gamma_5 P^\mu \\
&= 0. \quad (3.6)
\end{aligned}$$

Here, M_G, m_n, m denote masses of the gauge boson, the internal fermion, and the down-type quark, respectively. Q_ψ denotes the electric charge of internal fermion. x, y are Feynman parameters and $X \equiv x + y$. P_μ is defined as the sum of the external momenta for fermions, $P_\mu \equiv p_\mu + p'_\mu$. In the last diagram of the gauge boson self-energy, the plus(minus) sign corresponds to the diagram where $W_\mu(X_\mu)$ boson propagates in the loop, respectively. In all amplitudes, we used the property that Feynman parameter integral of an odd function of $x - y$ vanishes.

In order to arrive at the above expressions, the numerator of the integrand is calculated as

$$\begin{aligned}
&(aL + bR) \gamma_\nu (\not{k} + \not{p}' + m_n) \gamma^\mu (\not{k} + \not{p} + m_n) \gamma^\nu (cL + dR) \\
&\supset -(ad - bc) \gamma_5 (x - y) (1 - X) m P^\mu + 2(ac - bd) m_n \gamma_5 (1 - X) P^\mu.
\end{aligned}$$

In the above calculation, the momentum shift $k \rightarrow k - xp' - yp$ is performed and $\supset$ means that terms relevant for the fermion EDM are extracted. The equation of motion for the external fermion is also

utilized

$$\bar{\psi}(p')\gamma_5(x\not{p}' + y\not{p})\psi(p) \rightarrow (-x + y)m\bar{\psi}(p')\gamma_5\psi(p). \quad (3.7)$$

Applying the possible interaction vertices described in [40] to these formulae derived above, we can obtain the amplitudes of the EDM in a straightforward way and list up them by classifying into the neutral current sector, charged current sector and gauge boson self-energy sector. Concerning the mode indices in the amplitude, the summation $\sum_{l,m,n=1}^{\infty}$ should be understood. In our calculation, we adopt approximations $m_W, m \ll 1/R$ and the results are shown at the leading order of $\mathcal{O}(m_W^2)$.

As will be seen below, all of the standard model diagrams have no contributions to the EDM at one-loop level, which is consistent with the well-known fact that the EDM in the standard model is generated at least at 3-loop level [43].

3.1 Neutral current sector

3.1.1 KK mode photon exchange

$$= \frac{e}{3} \int \frac{d^4k}{(2\pi)^{4i}} \int_0^1 dx \int_0^{1-x} dy \frac{2 \frac{g_4^2}{3} \frac{M_n^2}{m_n^2} \frac{\pi R M}{1 - e^{-2\pi R M}} \left(\frac{I_3}{\pi R}\right)^2 \frac{m_l \tilde{m}_{nl}}{m_n^2 - m_l^2} (-1)^{n+m} 4(1-X)m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.8)$$

3.1.2 KK mode photon partner exchange

$$= -\frac{e}{3} \int \frac{d^4k}{(2\pi)^{4i}} \int_0^1 dx \int_0^{1-x} dy \frac{2 \frac{g_4^2}{3} \frac{\pi R M}{e^{2\pi R M} - 1} \left(\frac{I_4}{\pi R}\right)^2 \frac{m_n \tilde{m}_{nl}}{m_n^2 - m_l^2} (-1)^{n+m} X m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.9)$$

3.1.3 Higgs exchange

$$= \frac{e}{3} \int \frac{d^4k}{(2\pi)^{4i}} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 I_5^2 \frac{m_l \tilde{m}_{nl}}{m_n^2 - m_l^2} X m_n (-1)^n}{[k^2 - X m_n^2]^3} \gamma_5 P_\mu. \quad (3.10)$$

3.1.4 KK mode Higgs exchange

$$= \frac{e}{3} \int \frac{d^4k}{(2\pi)^{4i}} \int_0^1 dx \int_0^{1-x} dy \frac{2 g_4^2 I_6^2 \left(\frac{M_n}{\pi R m_n}\right)^2 \frac{\pi R M}{e^{2\pi R M} - 1} \frac{m_l \tilde{m}_{nl}}{m_n^2 - m_l^2} (-1)^{n+m} X m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.11)$$

3.1.5 KK mode Higgs partner exchange

$$= -\frac{e}{3} \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{8g_4^2(1-X)m_n\gamma_5 P_\mu}{[k^2 - X m_n^2 - (1-X)M_m^2]^3}$$

$$\times \left[\frac{1}{2} \sqrt{\frac{\pi R M}{e^{2\pi R M} - 1}} \frac{\hat{m}_l}{m_l} \frac{I_4 I_2}{\sqrt{\pi R}} ((-1)^{l+m+n} - 1) - \frac{\pi R M}{e^{2\pi R M} - 1} \left(\frac{I_4}{\pi R} \right)^2 \frac{m_n \tilde{m}_{nl}}{m_n^2 - m_l^2} (-1)^{n+m} \right]. \quad (3.12)$$

3.1.6 KK mode Z boson exchange

$$= \frac{e}{3} \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\pi R M}{e^{2\pi R M} - 1} \frac{m_n \tilde{m}_{nl}}{m_n^2 - m_l^2} \left(\frac{I_4}{\pi R} \right)^2 (-1)^{n+m} \left(\frac{M_m^2}{m_n^2} + 1 \right) 4(1-X)m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.13)$$

3.1.7 KK mode neutral NG boson ϕ_y exchange

$$= \frac{e}{3} \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 X m_n (-1)^{n+m} \gamma_5 P_\mu}{[k^2 - X m_n^2 - (1-X)M_m^2]^3}$$

$$\times \frac{\pi R M}{e^{2\pi R M} - 1} \left[\left(\frac{I_4}{\pi R} \right)^2 \frac{m_n \tilde{m}_{nl}}{m_n^2 - m_l^2} - \left(\frac{I_6}{\pi R} \right)^2 \left(\frac{M_n}{m_n} \right)^2 \frac{m_l \tilde{m}_{nl}}{m_n^2 - m_l^2} \right]. \quad (3.14)$$

3.1.8 Zero mode neutral NG boson ϕ_y exchange

$$= -\frac{e}{3} \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 I_5^2 \frac{m_l \tilde{m}_{nl}}{m_n^2 - m_l^2} (-1)^n X m_n}{[k^2 - X m_n^2]^3} \gamma_5 P_\mu. \quad (3.15)$$

3.2 Charged current sector

3.2.1 KK mode W boson exchange

$$= \frac{8}{3} e \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi R M}{e^{2\pi R M} - 1}} \frac{I_4}{\sqrt{\pi R}} \left(\frac{M_m}{m_n} I_1 + I_2 \right) (1-X)m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.16)$$

3.2.2 KK mode X_μ boson exchange

$$= \frac{8}{3} e \int \frac{d^4 k}{(2\pi)^4 i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi R M}{e^{2\pi R M} - 1}} \frac{I_4}{\sqrt{\pi R}} \left(\frac{M_m}{m_n} I_1 + I_2 \right) (1-X)m_n}{[k^2 - X m_n^2 - (1-X)M_m^2]^3} \gamma_5 P_\mu. \quad (3.17)$$

3.2.3 KK mode X_y boson exchange

$$= -\frac{2}{3}e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{-g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \left((-1)^{l+m+n} \frac{I_4 I_2}{\sqrt{\pi R}} + \frac{M_n}{m_n} \frac{I_1 I_6}{\sqrt{\pi R}} \right) X m_n}{[k^2 - X m_n^2 - (1-X) M_m^2]^3} \gamma_5 P_\mu. \quad (3.18)$$

3.2.4 KK mode W_y boson exchange

$$= -\frac{2}{3}e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{-g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \left((-1)^{l+m+n} \frac{I_4 I_2}{\sqrt{\pi R}} + \frac{M_n}{m_n} \frac{I_1 I_6}{\sqrt{\pi R}} \right) X m_n}{[k^2 - X m_n^2 - (1-X) M_m^2]^3} \gamma_5 P_\mu. \quad (3.19)$$

3.3 gauge boson self-energy

3.3.1 KK mode W_μ boson self energy diagram

$$= e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \frac{I_4}{\sqrt{\pi R}} \left(\frac{M_m}{m_n} I_1 + I_2 \right) (6-3X) m_n}{[k^2 - X M_m^2 - (1-X) m_n^2]^3} \gamma_5 P_\mu. \quad (3.20)$$

3.3.2 KK mode X_μ boson self energy diagram

$$= e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \frac{I_4}{\sqrt{\pi R}} \left(\frac{M_m}{m_n} I_1 + I_2 \right) (6-3X) m_n}{[k^2 - X M_m^2 - (1-X) m_n^2]^3} \gamma_5 P_\mu. \quad (3.21)$$

3.3.3 KK mode X_y boson self energy diagram

$$= -e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{-g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \left((-1)^{l+m+n} \frac{I_4 I_2}{\sqrt{\pi R}} + \frac{M_n}{m_n} \frac{I_1 I_6}{\sqrt{\pi R}} \right) (1-X) m_n}{[k^2 - X M_m^2 - (1-X) m_n^2]^3} \gamma_5 P_\mu. \quad (3.22)$$

3.3.4 KK mode W_y boson self energy diagram

$$= e \int \frac{d^4k}{(2\pi)^4i} \int_0^1 dx \int_0^{1-x} dy \frac{g_4^2 \frac{\hat{m}_l}{m_l} \sqrt{\frac{\pi RM}{e^{2\pi RM}-1}} \left((-1)^{l+m+n} \frac{I_4 I_2}{\sqrt{\pi R}} + \frac{M_n}{m_n} \frac{I_1 I_6}{\sqrt{\pi R}} \right) (1-X) m_n}{[k^2 - X M_m^2 - (1-X) m_n^2]^3} \gamma_5 P_\mu. \quad (3.23)$$

Various integrals appearing in the amplitudes are defined as follows.

$$I_1 \equiv \int_{-\pi R}^{\pi R} dy \frac{1}{(\sqrt{\pi R})^3} S_l(y) C_m(y) S_n(y), \quad (3.24)$$

$$I_2 \equiv \int_{-\pi R}^{\pi R} dy \frac{1}{(\sqrt{\pi R})^3} \frac{M_n}{m_n} S_l(y) S_m(y) \left(C_n(y) - \frac{MR}{n} \varepsilon(y) S_n(y) \right), \quad (3.25)$$

$$I_3 \equiv \int_{-\pi R}^{\pi R} dy e^{-M|y|} C_m(y) \left(C_n(y) - \frac{MR}{n} \varepsilon(y) S_n(y) \right), \quad (3.26)$$

$$I_4 \equiv \int_{-\pi R}^{\pi R} dy e^{M|y|} S_m(y) S_n(y), \quad (3.27)$$

$$I_5 \equiv \int_{-\pi R}^{\pi R} dy \frac{M_n}{\sqrt{\pi R} m_n} e^{-M|y|} \sqrt{\frac{M}{1 - e^{-2\pi MR}}} \left(C_n(y) + \frac{MR}{n} \varepsilon(y) S_n(y) \right), \quad (3.28)$$

$$I_6 \equiv \int_{-\pi R}^{\pi R} dy C_m(y) \left(C_n(y) - \frac{MR}{n} \varepsilon(y) S_n(y) \right) \quad (3.29)$$

with $S_n(y) = \sin(\frac{n}{R}y)$ and $C_n(y) = \cos(\frac{n}{R}y)$.

It is very interesting that the neutron EDM is generated already at 1-loop although it is generated at 3-loop in the case of standard model. We can see that the EDM contributions from neutral current sector are due to the mixing terms between different nonzero KK modes of down quark, which is proportional to $\tilde{m}_{nl}$. On the other hand, the EDM contributions from the charged current sector are due to the mixing terms between a zero mode and nonzero KK modes of down quark, which is proportional to $\hat{m}_n$. Since these two mass parameters $\tilde{m}_{nl}$ and $\hat{m}_n$ are proportional to both of the bulk mass M and the W-boson mass m_W (see, (2.17)), the EDM vanishes if the bulk mass is zero while the Higgs VEV is nonzero, and vice versa. This is consistent with the general discussion described in the introduction on how CP is violated.

4 Numerical estimation of EDM from nonzero KK modes

We move to numerical calculation of neutron electric dipole moment. We expect that up quark electric dipole moment d_u vanishes in this model, since there is no right-handed up quark and the operator describing up quark electric dipole moment $\langle H \rangle \bar{u}_{L(R)} \sigma_{\mu\nu} \gamma^5 u_{R(L)} F^{\mu\nu}$ does not exist. Thus, the neutron electric dipole moment d_n in this model is written as follows:

$$d_n = \frac{4}{3} d_d - \frac{1}{3} d_u = \frac{4}{3} d_d. \quad (4.1)$$

To reproduce down quark Yukawa coupling, we must set a bulk mass parameter so as to satisfy the following relation:

$$\frac{m}{m_W} = \frac{2\pi RM}{\sqrt{(1 - e^{-2\pi RM})(e^{2\pi RM} - 1)}} \sim \frac{4 \sim 8 \text{ MeV}}{80 \text{ GeV}}. \quad (4.2)$$

Thus, we set the bulk mass as $2\pi RM = 25.5$ ($m = 6$ MeV is taken).

Here, only the numerical results are shown. The contributions from the neutral current and the charged current processes to the EDM are denoted by $d(\text{N.C.})$ and $d(\text{C.C.})$ and are obtained as

follows.

$$\begin{aligned}
d(\text{N.C.}) &\sim \frac{16}{9}e^3 \left(\frac{MR}{\pi}\right)^4 R^2 m_W (-8.3 \times 10^{-7}), \\
d(\text{C.C.}) &\sim -\frac{2}{9}e^3 \frac{(MR)^3}{\pi^3} R^2 m_W (2.12 \times 10^{-5}) + \frac{16}{9}e^3 \frac{(MR)^4}{\pi^4} R^2 m_W (8.0 \times 10^{-7}).
\end{aligned} \tag{4.3}$$

Combining these results we obtain the final result on the contribution from nonzero KK mode $d(\text{KK})$ as

$$d(\text{KK}) = d(\text{N.C.}) + d(\text{C.C.}) \sim -2.3 \times 10^{-23} (R m_W)^2 [e \cdot \text{cm}]. \tag{4.4}$$

We require that the contribution of KK mode $\frac{4}{3}d(\text{KK})$ is less than the experimental upper bound [44],

$$\frac{4}{3} \cdot 2.3 \times 10^{-23} (R m_W)^2 [e \cdot \text{cm}] < 2.9 \times 10^{-26} [e \cdot \text{cm}] \tag{4.5}$$

which gives a lower bound for the compactification scale

$$\frac{1}{R} > 33 m_W \simeq 2.6 \text{ TeV}. \tag{4.6}$$

5 Summary

In this paper we studied the neutron electric dipole moment (EDM) in a five dimensional $SU(3)$ gauge-Higgs unification compactified on $M^4 \times S^1/Z_2$ space-time including massive fermions belonging to the triplet of $SU(3)$. The smallness of the quark Yukawa coupling is realized by introducing a Z_2 -odd bulk mass $M\epsilon(y)$. We pointed out that to realize the CP violation is a non-trivial task in the gauge-Higgs unification scenario where the Yukawa coupling is originally gauge coupling, which is of course real. We identified the transformation properties of each field under P and CP transformations, since to get non-vanishing EDM both P and CP symmetries have to be broken, though P is broken anyway by the orbifolding. We have found that since the theory itself is CP symmetric, the unique source of the CP violation in our model is the VEV of the Higgs, the extra space component of the gauge field A_y . In such a sense, CP is broken spontaneously through the Hosotani mechanism[3]. We emphasized that actually to get physically the CP violating effect the interplay between the VEV of A_y and the bulk mass M is crucial. In fact in the hypothetical limit of $M \rightarrow 0$, it turned out that by suitable chiral transformation A_y becomes a field with even CP eigenvalue, whose VEV therefore does not break CP symmetry. From such a point of view both of the VEV and the bulk mass are the cause of the CP violation on an equal footing.

We then calculated the one-loop contributions to the neutron electric dipole moment as the typical example of the CP violating observable and found that the EDM appears already at the one-loop level, without invoking to the three generation scheme, in clear contrast to the case of the Standard Model where EDM appears only at the three-loop level. The explicit calculation has shown that one-loop contributions from nonzero KK modes to the neutron EDM are generated due to the mixing effects between different nonzero KK modes, and between a zero mode and nonzero KK modes. Also, the obtained EDM was proportional to the Higgs VEV and the bulk mass, which was consistent with what we discussed concerning the importance of their interplay to get CP violation.

Furthermore, we could confirm that the standard model contribution to the neutron EDM due to the Kaluza-Klein zero modes vanishes at the one-loop level, as we expect.

The fact that EDM appears already at the one-loop level suggests that we may be able to get a rather stringent lower bound on the compactification scale by the comparison with the data. This turns out to be the case. We could derive a rather stringent lower bound for the compactification scale, which is around 2.6 TeV, by comparing the contribution due to the nonzero Kaluza-Klein modes with the experimental data.
